# Discussion Overview

## Learning Objectives

- Highlight guidelines specific to initiating insulin therapy in type 1 and type 2 diabetes
- Underscore the pharmacokinetic attributes of currently-available insulin products
- Recognize and critique strategies related to insulin-specific management in type 1 and type 2 diabetes
- Highlight basic insulin pump operation and the goal of complimenting normal physiologic pancreatic function.
- Differentiate between the advantages and disadvantages of CSII vs. multiple daily injections for people with type 1 and type 2 diabetes.
- Discuss the benefits of CSII for a patient with insulin-requiring type 2 diabetes.

## Key Phrases/Terms

- **Physiologic versus Non-physiologic Therapies**
- **Standard Deviation**
- **Legacy Effect**
- **Time-in-Range**

# Trending Statistics

≈**5,000 Adult** and ≈**900 Pediatric**  
Board Certified Endocrinologists in the U.S.

≈**3,900 Clinically Active**

**84.1 million** with “Pre-diabetes”

**30.3 million** “Classic” diabetes

**1 Endocrinologist per ≈29,300 (Pre- + Diabetic)**

**Patients Nationwide**

**85% of Diabetes Care will require:**

**Health Care Providers beyond  
Endocrinologists**

- **Primary Care Physicians**
- **Physician Assistants**
- **Nurse Practitioners**

# “The Whole is Greater Than the Sum of Its Parts”

**Aristotle** (Greek philosopher/scientist; 384 B.C. → 322 B.C.)

**Defines the modern concept of Synergy** and the T.E.A.M. acronym:

**T**ogether, **E**verything **A**chieves **M**ore.

Applies to physics, engineering, agriculture, business, and .....

..... **the chemistry and biology of insulin**

# Evolution of a Therapeutic Breakthrough

## INSULIN: Landmark Discovery

## 96 Years of Pharmacologic Milestones

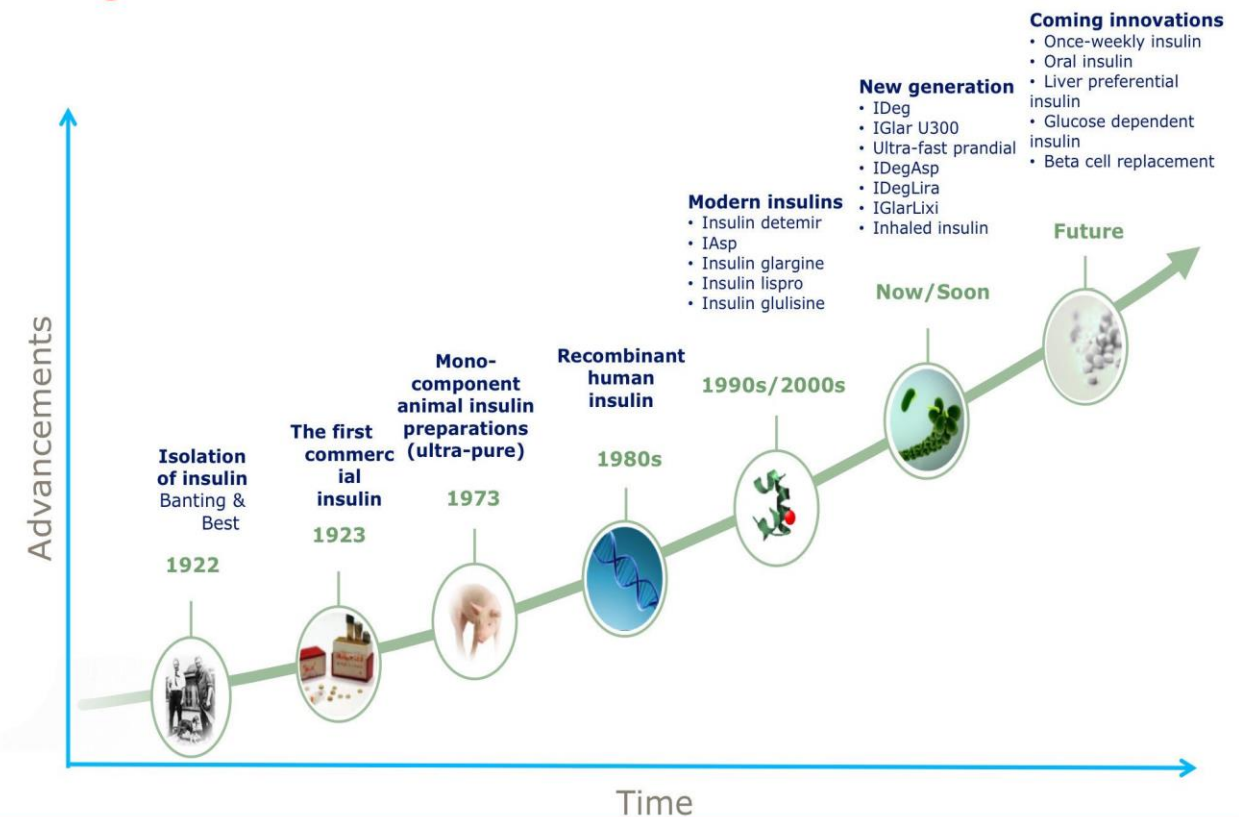

### Dr. Frederick Banting & Charles Best

- 1921 – discovered insulin using dogs
- 1922 – 14-yr-old boy with diabetes, near death, first person to receive insulin
- 1923 – Nobel prize

Insulin therapy development: A rich history, a good present, a bright future

On his discovery of Insulin...

Insulin is **not a cure** for diabetes; it is a treatment. It enables the diabetic to burn sufficient carbohydrates, so that proteins and fats may be added to the diet in sufficient quantities to provide energy for the economic burdens of life.

— Sir Frederick Grant Banting

# Greatest Historical Breakthroughs in Insulin Therapy

- **1973:** Development of **Mono-component “Human” insulin**

- **Purified pork insulin**; new standard in purity.
- **Enzymatic conversion: Alanine (B30) → Threonine**
- **Identical in structure to human insulin**

- **1978:** Advancement of **Recombinant DNA “Human” Insulin**

- Gene manipulation of **E. coli** to produce **Bio-synthetic human insulin**
- **Eliminated insulin allergy and immune-mediated lipodystrophy.**
- **Humulin R and Humulin N** (Eli Lilly)

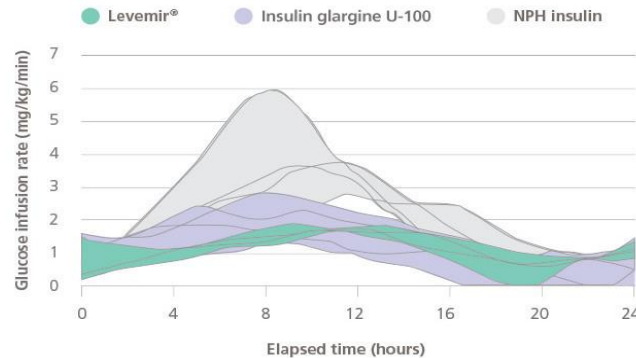

- **1995:** Expansion to **Insulin Analogues**

- **Laboratory grown** (*E. coli*/*Baker’s Yeast*) but **genetically altered** amino acid sequence)
- **Pharmaco-kinetic/-dynamic features** striving to simulate “**endogenous**” insulin
- **Lispro is the first analogue produced** – FDA approved 1996

# Primary Goal of Insulin Treatment Strategies

- Match pharmaco-kinetic/-dynamic profile of “endogenous insulin”:
  - Timing precision; adherence; fewer injections
  - Reduce within-/between-patient variability in plasma glucose

- Tight glycemic control:
  - Limit microvascular complications (**DCCT and UKPDS**)
  - **Reduce** glucose variability/**standard deviation** (**oxidative stress** → **O<sub>2</sub><sup>-</sup> free radicals** → **endothelial damage**)
  - Minimize “**Legacy Effect**”
  - Achieve “**Time-in-Range**” (**HbA1C???**)

- Minimal risk for exogenous side effects:

- hypoglycemia
- weight gain

- Achieve “**Prospective**” treatment models:

- Sliding Scale
- Split-Mixed (both insulins provide potential basal and prandial effects)
- Basal-Bolus
- Pump Infusion Therapy

Basal-Bolus vs. Sliding Scale Insulin Regimens

- What’s wrong with Sliding Scale by itself?
  - **Reactive Approach**- waiting until BG elevates
  - Causes rollercoaster effect for patient
  - Basal/bolus approach is **proactive**; more like normal insulin delivery
  - Basal bolus with correction should be used, not correction by itself in most cases.

The graphic shows a rollercoaster track with a car on it. The track starts with a small dip, then rises to a high peak, followed by a sharp drop and another smaller peak. This illustrates the 'rollercoaster effect' of a reactive sliding scale approach, where glucose levels fluctuate wildly. The text explains that a proactive basal-bolus approach is more like normal insulin delivery.

# Major Adverse Effects of Insulin

- **Hypoglycemia (unawareness)**
  - **DCCT Study (Type 1 Diabetes)**
    - Severe hypoglycemia in **26% of patients**
    - **43% of episodes nocturnal**
  - **UKPDS Study (Type 2 Diabetes)**
    - Insulin cohort: 2% of patient with at least 1 **severe** episode/year
- **Weight Gain (over “insulinization”; hypoglycemia/defensive snacking)**
  - **DCCT Study (Type 1 Diabetes)**
    - Intensive cohort with **≈ 10.5 lb. increase**
  - **UKPDS Study (Type 2 Diabetes)**
    - Insulin Cohort with **≈ 5.1 lb. increase**
- **Progression of Retinopathy with rapid glycemic control**
  - **Osmotic Hypothesis**: rapid decline in plasma glucose shifts water from a higher osmotic pressure interstitium to a lower intravascular osmotic space
  - **Synergistic Hypothesis**: **insulin amplification** + expression of vascular endothelial growth factor (by ischemic vessels) promotes retinal vascular proliferation.
  - **Higher Risk = proliferative retinopathy + HbA1C ≥ 10%**

# 1982-1993 DCCT Study: 3-fold increase in Hypoglycemia

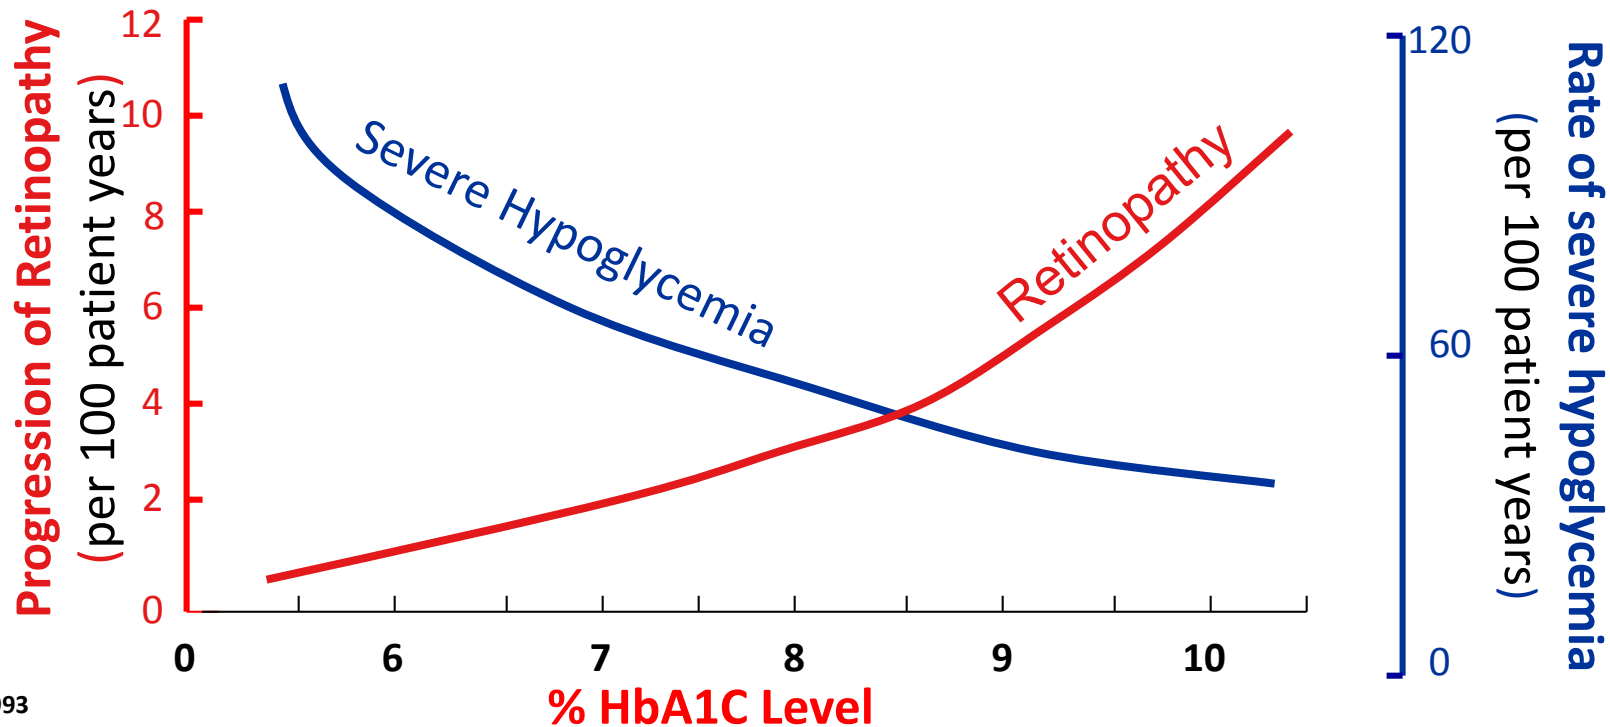

Trade-off between: Reducing Complications & Minimizing Hypoglycemia

**Patients used:** Regular insulin /Intensive therapy via **Multiple Injections** or **Insulin Pump**

Intensive Glycemic Control Reduced Microvascular complications overall → ≈60%:

- **Retinopathy** 63%
- **Neuropathy** 60%
- **Nephropathy** 54%

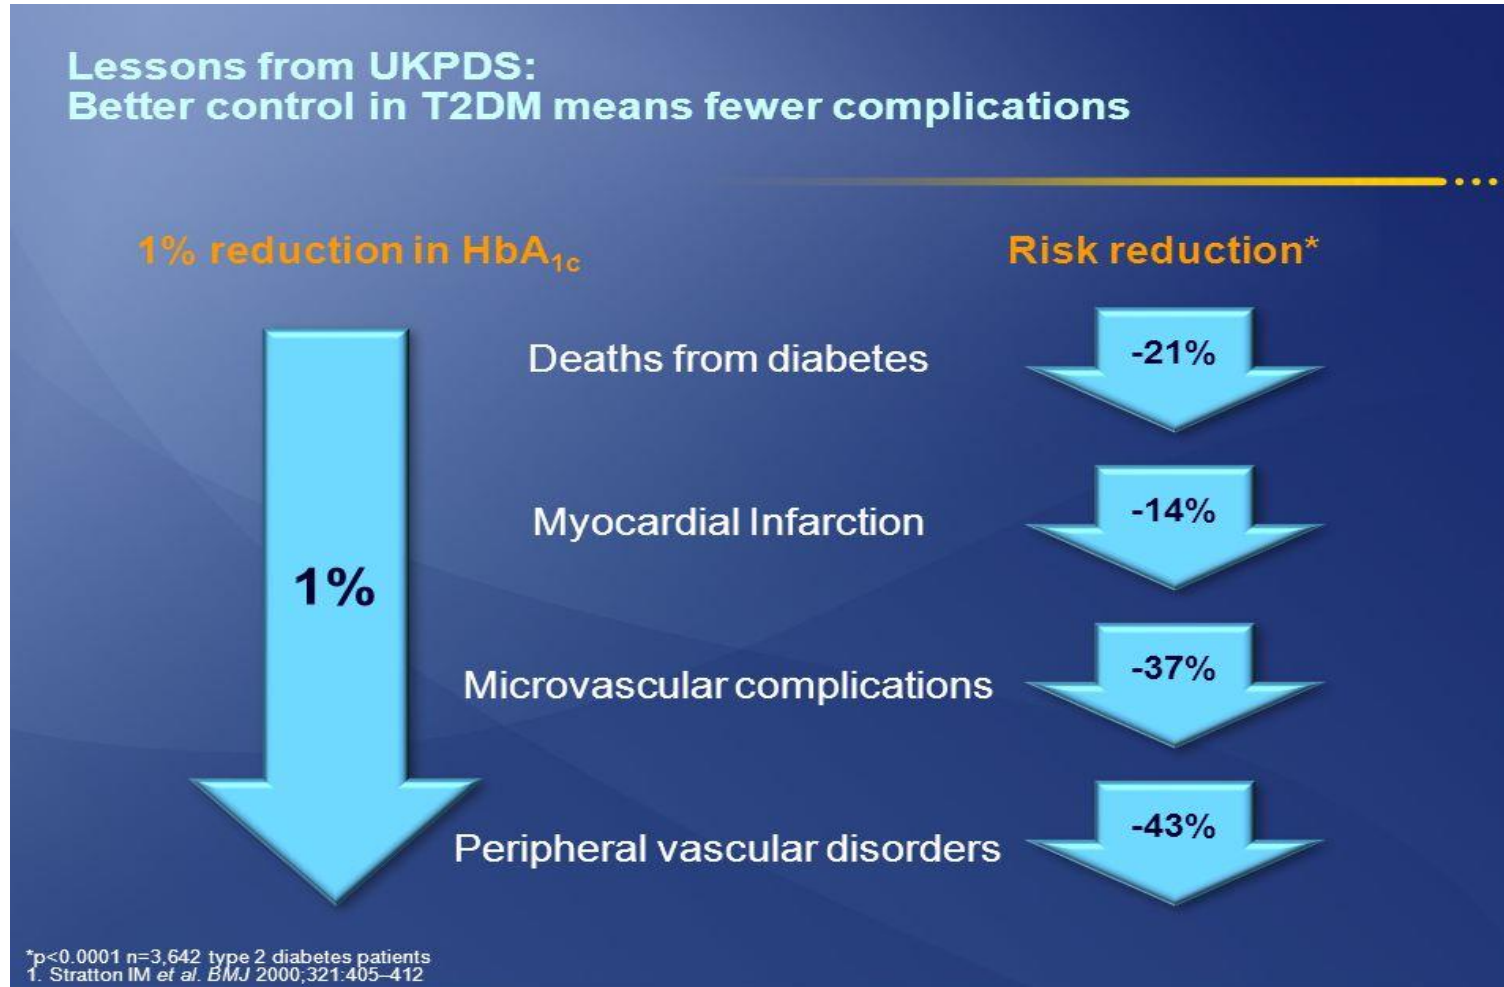

**By End of Study 42% of Intensively-Managed Patients on CSII Therapy**

1977-1997:

**United Kingdom Prospective Diabetes Study for Type 2 Diabetes  
 (“Newly Diagnosed Patients”)  
 Intensification of Therapy (i.e. sulfonylureas, insulin, MDI therapy)**

**HbA1C Reduction of  $\approx 1.0\%$**

# Behavioral, Distribution and Absorption Considerations

- **Molecular Character:**

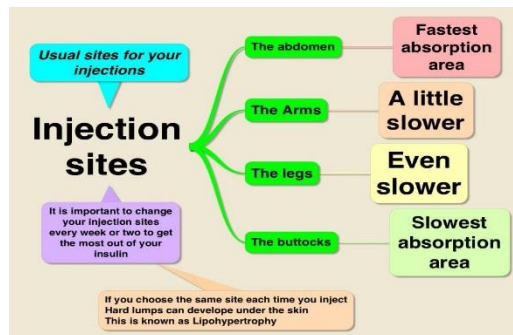

- Human **non-analogue** versus **analogue** insulin → altered kinetic behavior
- **Fatty-acid side-chain:**
  - dictates self-association/reversible albumin binding features
  - influences portal/peripheral/CNS distribution

- **Product concentration:**

- **U-100, U-200, U-300, U-500**
- absorption rate inverse to concentration

- **Injection sites:**

- **Formulation design:**

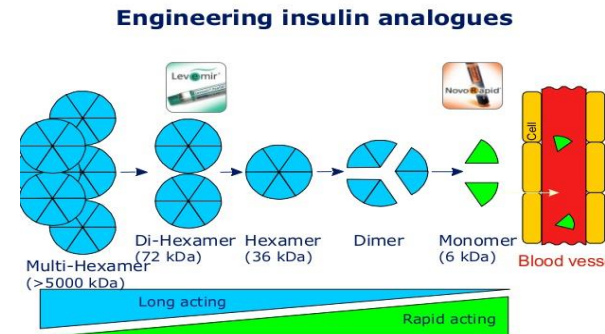

- **Protamination:** “crystalline-based” protracted absorption (limited/variable) **NPH Insulin**
- **pH-altered precipitation:** protracted absorption (extended/less-variable) **Glargine Insulin (Lantus)**
- **Non-precipitant (Fatty-acid side chain):** protracted/reproducible absorption kinetics

**Detemir Insulin (Levemir)**

- **Zinc, Phenol, m-cresol components:**

- Self-association/conformational properties in-solution: multi-hexamers → di-hexamers → hexamers → monomers
- Dissociation properties SQ → active insulin monomers

**Degludec Insulin (Tresiba)**

# The Ideal Analogue Insulin

## Rapid-acting agents:

- Replicate **first- and second-phase** endogenous kinetics
- **High hexameric stability** in solution; **rapid dissociation into monomers** post-SQ injection
- Match "action time" for meals
- **Predictable end-point** to minimize residual insulin conflicts (hypoglycemia)
- Prevent **ramifications of post-prandial hyperglycemia**:
  - Insulin "Over Correction" → post-prandial hypoglycemia (Pump; Basal-Bolus regimens)
  - Post-prandial-related CV Risk:
    - HbA1C 1% ↑ = **50%** CV↑ = Type 1 DM
    - HbA1C 1% ↑ = **7.5%** CV↑ = Type 2 DM

## 24-hour Basal agents:

- Achieve **steady-state** pharmacokinetics/dynamics
- **Low peak:trough ratio**
- **Duration of action comfortably exceeds 24-hours**
- Dosing frequency **not to exceed once daily**
- **Low variability of action** from injection to injection
- **Able to mix** with Rapid-acting insulin

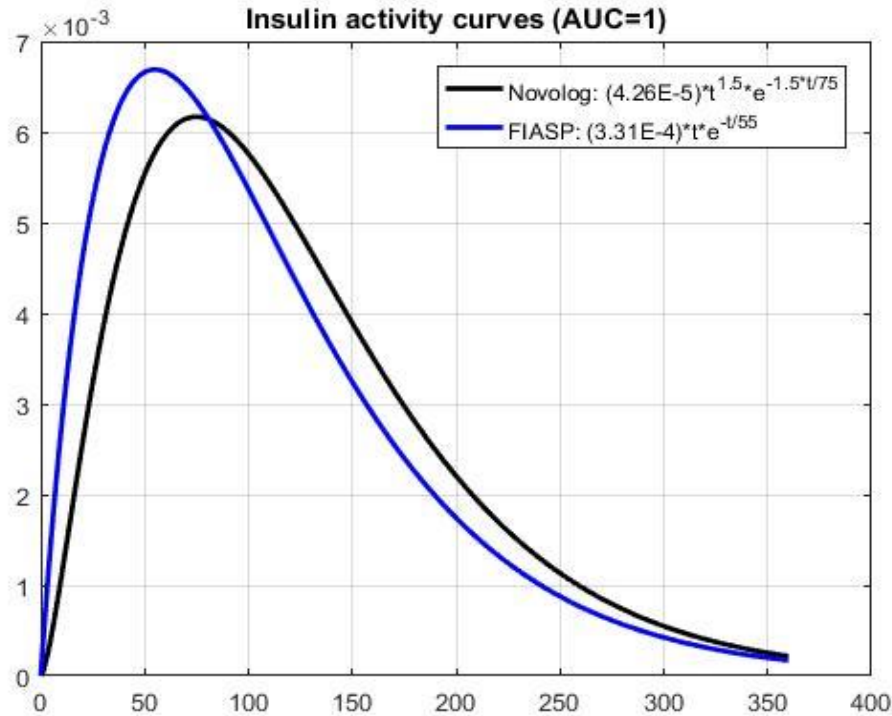

# Endogenous Insulin Kinetics

- Secretion is Bi-phasic
- Prandial First-phase Insulin Release:
  - **begins within 2 minutes** of nutrient ingestion
  - **“buffers” postprandial glucose “spike”**
  - **earliest “flaw” in beta-cell function**
- Prandial Second-phase Insulin Release:
  - sustained until normoglycemia is restored
  - **suppresses hepatic glucose production**
- Basal Insulin Maintenance
  - $\approx$  50% of our total daily insulin;
  - **suppresses lipolysis, proteolysis, and glycogenolysis**

# Ideal Rapid and Basal Insulins

## Rapid- and Long-Acting Insulin Profiles

# The Ideal Analogue Insulin

## Rapid-acting agents:

	ONSET	PEAK	DURATION	SPECIFICS
<b>Regular insulin:</b>	<b>30 min.</b>	3-4 hrs.	6-8 hrs.	Zinc-insulin crystals in sterile, clear solution
<b>Humalog insulin:</b>	15 min.	75-90 min.	3½-4 hrs.	B-chain <b>inversion</b> of Pro <sup>28</sup> and Lys <sup>29</sup>
<b>Novolog <i>RAPID-acting</i> insulin:</b>	10-15 min.	40-75 min.	3½-4 hrs.	Single B-chain <b>substitution</b> Proline <sup>28</sup> → Aspartic acid
<b>Apidra insulin (ZINC-FREE)</b>	< 10 min.	60 min.	2-4 hrs.	B-chain <b>dual substitution</b> Lysine <sup>3</sup> → Asparagine and Glutamic acid <sup>29</sup> → Lysine
<b>Novolog <i>FAST-acting</i> insulin: (FIASP)</b>	<b>2.5 min.</b>	1-3 hrs.	3-4 hrs.	<b>NICOTINAMIDE</b> accelerates absorption + <b>ARGININE</b> stabilizer

## 24-hour Basal agents:

	ONSET	PEAK	DURATION	SPECIFICS
<b>Toujeo insulin:</b>	6 hrs.	Minimal Peak	24-36 hrs.	<b>COMPACT SQ DEPOT</b> reduces re-dissolution rate; U-300 formulation
<b>Tresiba insulin:</b>	1-4 hrs.	<b>No Peak</b>	<b>up to 42 hrs.</b>	<b>“STEADY-STATE”</b> kinetics; <b>ABLE TO MIX</b> ; <u>20% intra-patient variability</u>
<b>Lantus insulin:</b>	2-4 hrs.	Minimal Peak	22-24 hrs.	<b>SQ PRECIPITANT</b> ; Near-peakless profile; <u>46% intra-patient variability</u>
<b>Levemir insulin:</b>	2-3 hrs.	6-8 hrs.	22-24 hrs.	<b>NON-PRECIPITANT</b> ; Reversible Albumin Binding; <u>27% intra-patient variability</u>

# The Ideal Analogue Insulin

## Rapid-acting agents:

	ONSET	PEAK	DURATION	SPECIFICS
Regular insulin:	30 min.	3-4 hrs.	6-8 hrs.	Zinc-insulin crystals in sterile, clear solution
Humalog insulin:	15 min.	75-90 min.	3½-4 hrs.	B-chain inversion of Pro <sup>28</sup> and Lys <sup>29</sup>
Novolog <i>RAPID-acting</i> insulin:	10-15 min.	40-75 min.	3½-4 hrs.	Single B-chain substitution Proline <sup>28</sup> → Aspartic acid
Apidra insulin (ZINC-FREE)	< 10 min.	60 min.	2-4 hrs.	B-chain dual substitution Lysine <sup>3</sup> → Asparagine and Glutamic acid <sup>29</sup> → Lysine
Novolog <i>FAST-acting</i> insulin: ( <i>FIASP</i> )	<b>2.5 min.</b>	1-3 hrs.	3-4 hrs.	<b>NICOTINAMIDE</b> accelerates absorption + <b>ARGININE</b> stabilizer

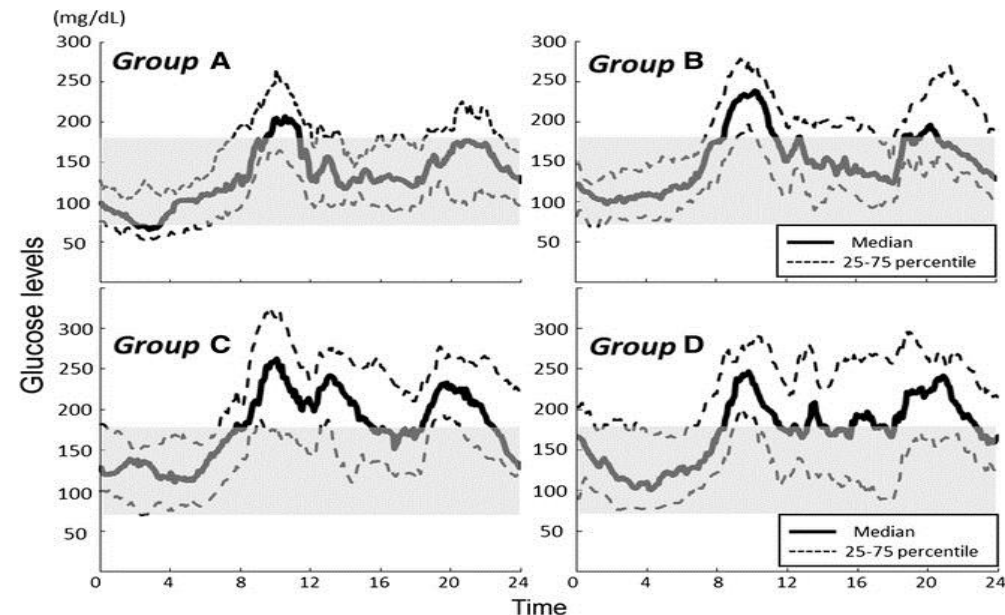

## 24-hour Basal agents:

	ONSET	PEAK	DURATION	SPECIFICS
Toujeo insulin:	6 hrs.	Minimal Peak	24-36 hrs.	COMPACT SQ DEPOT reduces re-dissolution rate; U-300 formulation
<b>Tresiba insulin:</b>	1-4 hrs.	<b>No Peak</b>	<b>up to 42 hrs.</b>	<b>“STEADY-STATE”</b> kinetics; <b>ABLE TO MIX</b> ; <u>20% intra-patient variability</u>
Lantus insulin:	2-4 hrs.	Minimal Peak	22-24 hrs.	SQ PRECIPITANT; Near-peakless profile; <u>46% intra-patient variability</u>
Levemir insulin:	2-3 hrs.	6-8 hrs.	22-24 hrs.	NON-PRECIPITANT; Reversible Albumin Binding; <u>27% intra-patient variability</u>

# Hypoglycemia: The Limiting factor to Glycemic Control

- 101 Type 1 diabetic patients receiving basal-bolus insulin therapy enrolled
- CGM data collected to provide insight into glycemic variability.
- Patients **stratified equally by HbA1c values with CGM data** demonstrating
  - All HbA1c subgroups exhibit similar patterns of glycemic variability and SD of  $\approx 50\text{--}60$  mg/dL
  - The lower the HbA1c value, the longer the duration of hypoglycemia and nocturnal (23:00–6:00) hypoglycemia
  - **Study implication: A lower HbA1c is not associated with a lower SD → but may lead to increased hypoglycemic episodes.**

- Group A: HbA1c  $\leq 7.2$  %
- Group B: 7.2 %  $\rightarrow$  8.1 %
- Group C: 8.2 %  $\rightarrow$  9.1 %
- Group D: HbA1c  $> 9.2$  %

Journal of Diabetes Complications. 2005 May-Jun;19(3):178-81.

## Should minimal blood glucose variability become the gold standard of glycemic control?

Irl B. Hirsch and Michael Brownlee

### **Abstract:**

*The DCCT Trial established HbA1C as the gold standard of glycemic control, with levels  $\leq 7\%$  deemed appropriate for reducing the risk of vascular complications .....*

..... Yet, even when A1Cs were comparable between intensively treated subjects and their conventionally treated counterparts, the latter group experienced a markedly higher risk of progression to retinopathy over time.

Our speculative explanation, **based on the discovery that hyperglycemia-induced oxidative stress is the chief underlying mechanism of glucose-mediated vascular damage**, was that **glycemic excursions were of greater frequency and magnitude among conventionally treated patients**, who received fewer insulin injections.

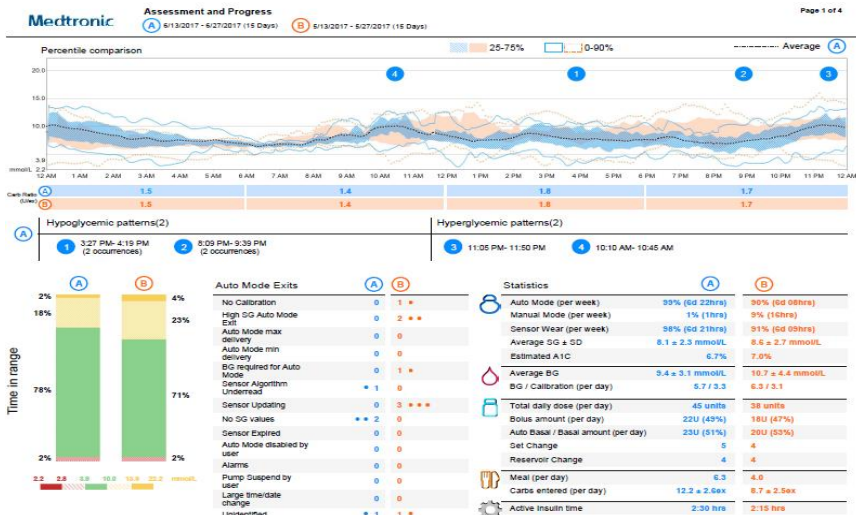

Subsequent **studies correlating the magnitude of oxidative stress with fluctuating levels of glycemia support the hypothesis that glucose variability**, considered in combination with A1C, **may be a more reliable indicator of blood glucose control** and the risk for long-term complications than mean A1C alone.

# Should Minimal Blood Glucose Variability (“Time in Range”) Become the Gold Standard

## “Time In Range” CGM Bar Graph Summary

## CGMS Analysis: HbA1C 6.1 → 6.3% MDI Therapy

# Legacy Effect: Contribution of HbA1C Over Time

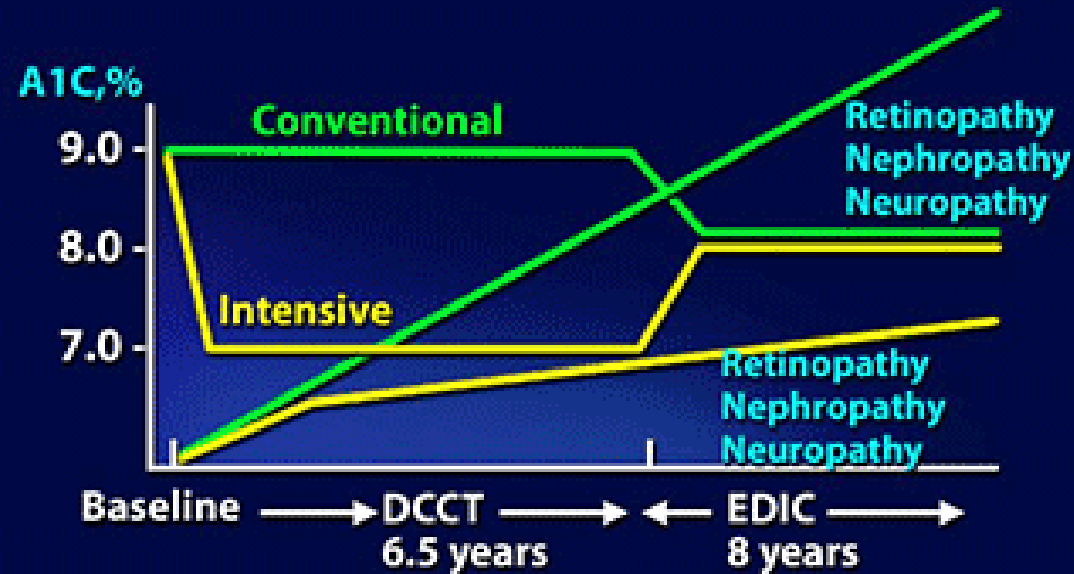

Relative contribution of HbA1c values at different past-points in time to future risk of retinopathy progression

For HbA1C values 2.4 years ago, the relative contribution is  $\approx 80\%$ .

For HbA1C values of 6.5 and 8.4 years ago, the contribution is 50% and 25% respectively.

# DCCT: Legacy Effect of Earlier Glucose Control

## Schematic Course of DCCT/EDIC Intensive and Conventional Groups

# UKPDS: Legacy Effect of Earlier Glucose Control

*After median 8.5 years post-trial follow-up*

Aggregate Endpoint	1997	2007
Any diabetes related endpoint	<i>RRR:</i> 12% <i>P:</i> 0.029	9% <b>0.040</b>
Microvascular disease	<i>RRR:</i> 25% <i>P:</i> 0.0099	24% <b>0.001</b>
Myocardial infarction	<i>RRR:</i> 16% <i>P:</i> 0.052	15% <b>0.014</b>
All-cause mortality	<i>RRR:</i> 6% <i>P:</i> 0.44	13% <b>0.007</b>

# Analogue Insulins: **Unique Considerations**

- **Insulin Aspart Rapid-acting (Novolog):**

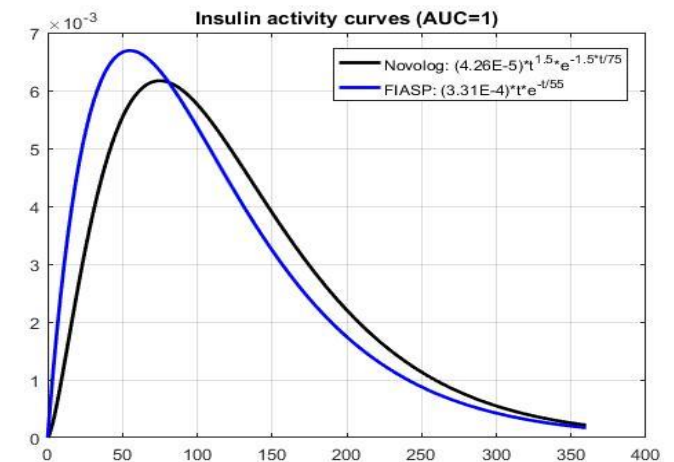

- Single amino acid substitution at **B28** (Proline → Aspartic Acid)
  - Humalog is a “molecular reversal” of proline (B28) and lysine (B29)
- **Zinc-based** product; **pH 7.2-7.6** (Humalog pH 7.0-7.8)
- Comparatively faster onset compared to Humalog
- **Administer 5-10 min. before meal** (Humalog 15 min.)

- **Insulin Glulisine (Apidra):**

- “Dual Substitution”: Lysine → Asparagine (B3) and Glutamic acid → Lysine (B29)
- “Zinc-Free” formulation **accelerates dissociation rate**
- **Onset of action < 10 minutes**

- **Insulin Aspart *Fast-acting* (FIASP):**

- Novolog insulin product with **2.5 minute onset of action**
- **Nicotinamide** added to solution to accelerate absorption
- **Arginine** included as a “stabilizer”

# Analogue Insulins: **Unique Considerations**

- **Insulin Detemir (Levemir)**: FDA approved June 16, 2005 (Lantus April 20, 2000)

- Genetically crafted using Baker's Yeast (*Saccharomyces cerevisiae*)

- **Molecular Design:**

- 14-carbon fatty acid (*myristic acid*) moiety covalently bound to Lysine (B29)

Insulin Detemir (2004)

- Only insulin to exhibit a **weight-sparing effect**:

- “**Non-precipitant**” formulation offers **less within-subject variability** → less hypoglycemia

- **C-14 carbon moiety** facilitates **blood-brain-barrier penetration** → hypothalamic satiety centers

- **C-14 carbon moiety** encourages **reversible-albumin-binding capability** → hepatic insulin extraction → limits peripheral lipogenesis

# Analogue Insulins: **Unique Considerations**

- **Insulin Glargine U-300 (Toujeo)** – “concentrated” form of Glargine U-100
  - **Molecular Design:**
    - 2 arginine amino acids attached to B-chain C-terminus and A21 substitution (asparagine → glycine).
    - **Compact Insulin Formulation/smaller surface area**
    - Formulation reduces dissolution rate
    - “Near-Flat” PK/PD profile → more gradual onset → prolonged release.
  - Starting dose is 1:1 match with any current analogue basal agent or 80% of NPH dose.
  - Transitioning from Glargine U-300 → Glargine U-100: Glargine U-100 dose **≈80%** of Glargine U-300 dose.
  - **BRIGHT 24-week Study (June 2018):** Toujeo Non-Inferior compared to Tresiba:
    - HbA1C reduction
    - Hypoglycemic event rate (**23%**)
    - Hypoglycemic incidence rate (**26%**)

 A Smoother and Prolonged PK/PD Profile vs. Lantus®

# Analogue Insulins: **Unique Considerations**

- Insulin Degludec (**Tresiba**)

- **Molecular design:**

- Threonine (B-30) on insulin B-chain **cleaved**
- **16-carbon fatty diacid side chain** attached to Lysine (B-29) using Glutamate spacer.

- **25-hour ½-life**; 100% steady-state after 8 injections (**90% after 4 injections**)

- Peak level achieved by **8-12 hours**

- **Lasts up to 42-hours** (detected in blood → 96 hours).

- **SWITCH Study (July 2017): Tresiba with less Hypoglycemia/Nocturnal Hypoglycemia vs. Lantus**

- SWITCH 1 (Type 1 DM): **35% Overall; 36% Nocturnal**
- SWITCH 2 (Type 2 DM): **30% Overall; 42% Nocturnal**

### 1. Pharmaceutical formulation

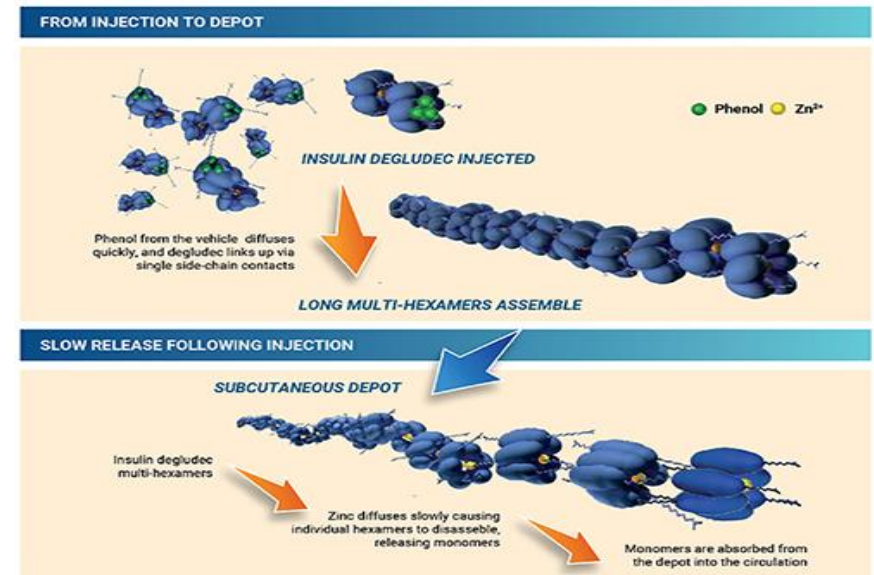

Injected; phenol diffuses

### 2. Subcutaneous depot

Zn<sup>2+</sup> diffuses

### 3. Circulatory absorption

# Tresiba Mechanism of Action

# Benefits of Early Insulin Therapy

- **Preserve Beta-cell function:**
  - restoration of “first-phase” insulin release?
- **Improve Lipid Metabolism**
- **Reduced mortality Post-MI:**
  - Post-prandial glycemic control?
- **Early control → “anti-inflammatory” mechanisms**, reducing macrovascular/microvascular risk:
  - Suppression of intranuclear transcription factor  $\kappa\beta$  → transcription of proinflammatory cytokines
- **Studies suggest: early tight control** achieves and sustains glycemic stability for extended periods with less medication.
- **UKPDS (Type 2 DM): B-cell failure progressive**
  - At time of diagnosis – 50% normal beta-cell function likely exists
  - By the time insulin therapy implemented – 25% function exists
  - **53% of patients treated with SUs** required insulin therapy by 6-years → 80% by 9-years
- Reduced morbidity → Net cost reduction
- Diabetes-related costs **≈15%** of the U.S. health-care budget

# 2018 ADA General Recommendations: Pharmacological Therapy in Type 2 Diabetes

## Start with Monotherapy unless:

A1C is greater than or equal to 9%, **consider Dual Therapy.**

A1C is greater than or equal to 10%, blood glucose is greater than or equal to 300 mg/dL, or patient is markedly symptomatic, **consider Combination Injectable Therapy** (See Figure 8.2).

## Monotherapy Metformin

## Lifestyle Management

<b>EFFICACY*</b>	high
<b>HYPO RISK</b>	low risk
<b>WEIGHT</b>	neutral/loss
<b>SIDE EFFECTS</b>	GI/lactic acidosis
<b>COSTS*</b>	low

If A1C target not achieved after approximately 3 months of monotherapy, proceed to 2-drug combination (order not meant to denote any specific preference — choice dependent on a variety of patient- & disease-specific factors):

## Dual Therapy Metformin +

## Lifestyle Management

	Sulfonylurea	Thiazolidinedione	DPP-4 inhibitor	SGLT2 inhibitor	GLP-1 receptor agonist	Insulin (basal)
<b>EFFICACY*</b>	high	high	intermediate	intermediate	high	highest
<b>HYPO RISK</b>	moderate risk	low risk	low risk	low risk	low risk	high risk
<b>WEIGHT</b>	gain	gain	neutral	loss	loss	gain
<b>SIDE EFFECTS</b>	hypoglycemia	edema, HF, fxs	rare	GU, dehydration, fxs	GI	hypoglycemia
<b>COSTS*</b>	low	low	high	high	high	high

If A1C target not achieved after approximately 3 months of dual therapy, proceed to 3-drug combination (order not meant to denote any specific preference — choice dependent on a variety of patient- & disease-specific factors):

## Triple Therapy Metformin +

## Lifestyle Management

	Sulfonylurea +	Thiazolidinedione +	DPP-4 inhibitor +	SGLT2 inhibitor +	GLP-1 receptor agonist +	Insulin (basal) +
	TZD	SU	SU	SU	SU	TZD
or	DPP-4-i	or DPP-4-i	or TZD	or TZD	or TZD	or DPP-4-i
or	SGLT2-i	or SGLT2-i	or SGLT2-i	or DPP-4-i	or SGLT2-i	or SGLT2-i
or	GLP-1-RA	or GLP-1-RA	or Insulin <sup>§</sup>	or GLP-1-RA	or Insulin <sup>§</sup>	or GLP-1-RA
or	Insulin <sup>§</sup>	or Insulin <sup>§</sup>		or Insulin <sup>§</sup>		

If A1C target not achieved after approximately 3 months of triple therapy and patient (1) on oral combination, move to basal insulin or GLP-1 RA, (2) on GLP-1 RA, add basal insulin, or (3) on optimally titrated basal insulin, add GLP-1 RA or mealtime insulin. Metformin therapy should be maintained, while other oral agents may be discontinued on an individual basis to avoid unnecessarily complex or costly regimens (i.e., adding a fourth antihyperglycemic agent).

## Combination Injectable Therapy (See Figure 8.2)

# 2018 ADA General Recommendations: Pharmacological Therapy in Type 2 Diabetes

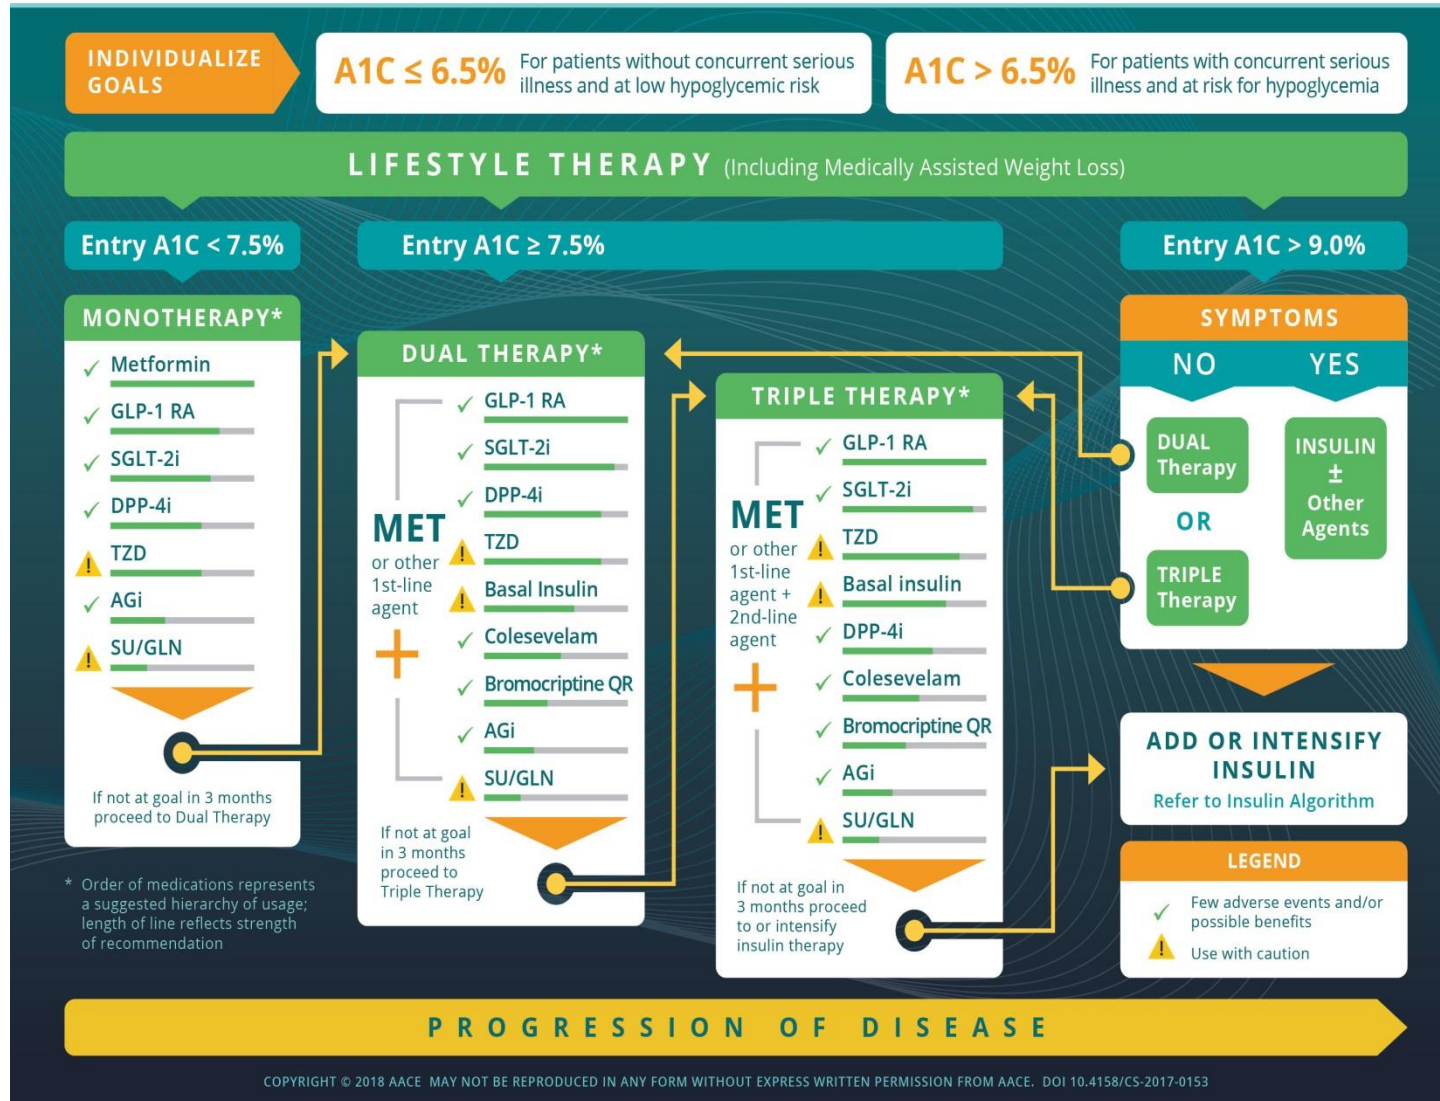

Combination injectable therapy for type 2 diabetes.

American Diabetes Association Dia Care 2017;40:S64-S74

# 2018 **AACE** General Recommendations: Pharmacological Therapy in **Type 2 Diabetes**

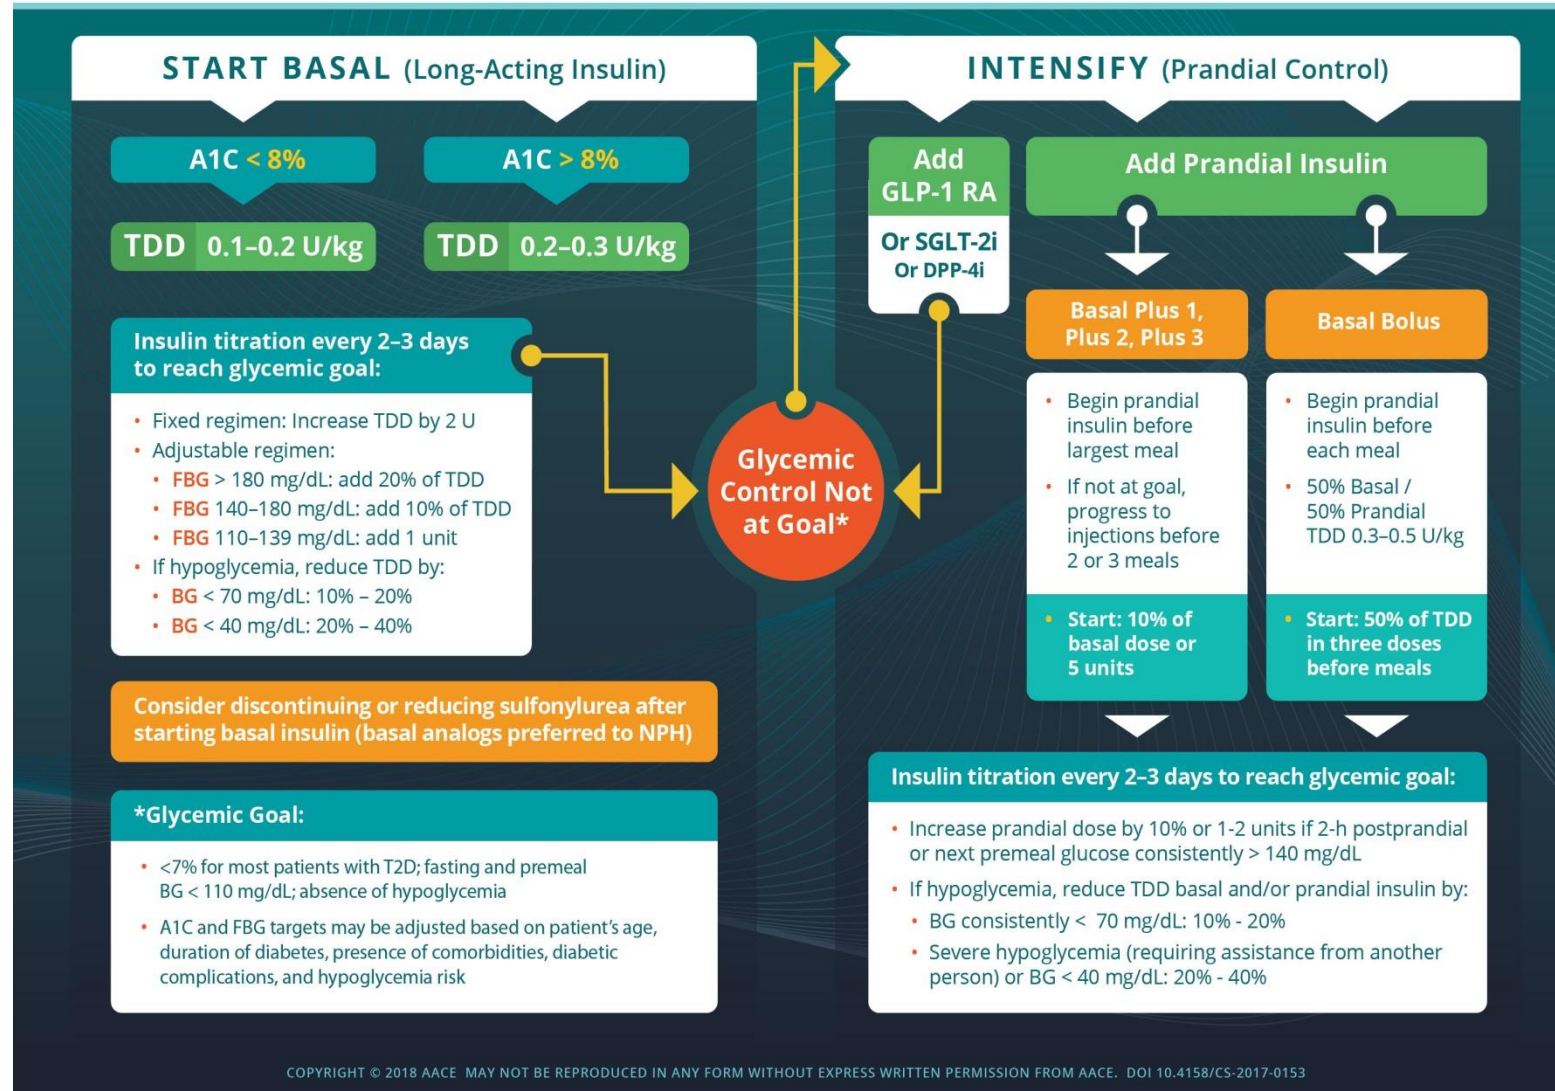

## Glycemic Control Algorithm

# 2018 **AACE** General Recommendations: Pharmacological Therapy in **Type 2 Diabetes**

## Algorithm for Adding/Intensifying Insulin

# Injectable Insulin Strategies

## Non-Physiologic

### • Split-Mixed Regimens:

- NPH + “**analogue**”-R or “**Human Regular**”-R”
- Each provides a **basal** and **prandial** effect
- Example → Morning mixed dose:
  - **R** contributes primary prandial-effect for breakfast, secondary prandial for lunch, and basal effect post-breakfast
  - **NPH** contributes basal-effect post-breakfast and Lunch, and primary prandial effect for lunch
- Requires meticulous attention to life-style organization
- Risk of “Late-morning overlap” → hypoglycemia

### • Sliding Scale Protocols:

- Should be avoided
- **Retrospective decision-making**

## Physiologic

### • Intensified Regimens

- True Basal Insulin + OAD agents
- True Basal Insulin + “selective Prandial” insulin
- **Basal-Bolus + “correction insulin”**
  - **Dosing flexibility**
  - **Predetermined** versus **Calculated** dosing
  - **More efficient post-prandial recovery**
  - **Prospective intervention**
  - **Avoid “Insulin Stacking”**

# Basal-Bolus Protocol

## Developing a “Recipe”

### Initiating SC Basal Bolus

- ◆ Starting total dose =  $0.5 \times \text{weight (kg)}$ 
  - If weight is 100 kg:  $0.5 \times 100 = 50 \text{ U}$
- ◆ Basal dose (insulin glargine) = 50% of starting dose at HS
  - $0.5 \times 50 = 25 \text{ U}$  at HS
- ◆ Bolus doses (analog preferred) = 50% of starting dose
  - $0.5 \times 50 = 25$  divided by 3 =  $\sim 8 \text{ U}$  PC (TID)
- ◆ Correction bolus =  $(\text{BG} - 100)/\text{CF}$ , where  $\text{CF} = 1700/\text{total daily insulin dose}$ ;  $\text{CF} = 30$

- When initiating Basal-Bolus regimen, **reduce calculated basal dose by 20%** to avoid hypoglycemia:
  - 1/3 will receive correct dose
  - 1/3 will need more
  - 1/3 will need less

## Clinical considerations:

- If using “correction insulin” between meals:
  - Remain aware of “**insulin-stacking**”
- If using “correction insulin”  $\leq 3\text{-hours}$  after a prandial dose, **reduce the “correction” by 50%**.
- If **exercising early** in the post-prandial period (1-3 hours), **reduce the prandial insulin dose by 75%**

# Typical Basal-Bolus Protocol

Mealtim Insulin: <b>FIASP</b>		Breakfast	Lunch	Dinner	Bedtime
		<b>8</b>	<b>8</b>	<b>8</b>	0
Correction: <b>FIASP</b>		Breakfast	Lunch	Dinner	Bedtime
	<80 mg/dL	0	0	0	0
	81-120 mg/dL	0	0	0	0
	121-160 mg/dL	<b>1</b>	<b>1</b>	<b>1</b>	0
	161-200 mg/dL	<b>2</b>	<b>2</b>	<b>2</b>	0
	201-250 mg/dL	<b>3</b>	<b>3</b>	<b>3</b>	0
	251-300 mg/dL	<b>4</b>	<b>4</b>	<b>4</b>	0
	301-350 mg/dL	<b>5</b>	<b>5</b>	<b>5</b>	0
	351-400 mg/dL	<b>6</b>	<b>6</b>	<b>6</b>	0
	>401 mg/dL	<b>7</b>	<b>7</b>	<b>7</b>	0
Basal Insulin: <b>TRESIBA</b>					<b>25</b>

# The Problem with “Sliding Scales”

- Little evidence for therapeutic efficacy
- Fluctuating glucose levels more harmful → oxidative stress → vascular endothelial damage
- Meal time insulin is “comprehensively” based on an isolated value (activity, caloric variability, “other stressors” NOT CONSIDERED)
- “Skipping a dose” when glucose is below a cutoff point leaves patient without insulin for hours
- Failure to individualize insulin protocols (i.e. age, weight, type of insulin, time of day, caloric variability, type of diabetes??)
- Incorporating basal insulin will not offset peaks and dips in blood glucose

# The Problem with “Sliding Scales”

## RABBIT 2: Glycemic Control With Basal-Bolus vs Sliding-Scale Insulin

\* $P < .01$ ; † $P < .05$ ; ‡Long-acting insulin (glargine) once daily + short-acting insulin (glulisine) before meals, total dose 0.4 unit/kg (BG 140-200 mg/dL) or 0.5 unit/kg (BG 201-400 mg/dL).

RABBIT 2=Randomized Study of Basal-Bolus Insulin Therapy in the Inpatient Management of Patients with Type 2 Diabetes. Umpierrez GE et al. *Diabetes Care*. 2007;30:2181-2186.

## SLIDING SCALE ONLY

RALS = Remote Automated Laboratory System.

# CGMS Technology reflects Interstitial Glucose

There is a greater difference when glucose is changing more rapidly.

dexcomG6™

The Future of Continuous Glucose Monitoring is Here!

**GUARDIAN™  
CONNECT CGM  
SYSTEM**  
WITH SUGAR.IQ™  
SMART ASSISTANT

# CGM sensors should be worn continuously

CGM indicated as an **adjunct to SMBG** and **does not replace SMBG**

## SMBG

(Self Monitoring Blood Glucose)  
"Snapshot" of Blood Glucose  
Potential 20% error rate

Measures Capillary Whole Blood glucose  
1-12+ Readings per day

## CGM

Rate change  
Pattern/Trend Recognition → 24-hour surveillance  
10.5% difference with paired laboratory reading

Measures Interstitial fluid glucose  
Up to 288 readings per day

- **CGM and SMBG measure glucose in different compartments**

# Insulin Pump Technology: A Brief History

**Dr. Arnold Kadish, 1963**

**First Prototype Insulin Pump**

**Delivers Insulin and Glucagon**

**1976**

**Mill Hill Infusor**

**Battery-operated syringe  
allows continuous release of insulin**

**1983**

**MiniMed® 502 Pump**

**Medtronic's First pump  
(502A improves size/programming)**

**1992**

**MiniMed® 506 Pump**

**Offered meal bolus memory  
and daily insulin totals**

# Insulin Pump Technology

November 2011

Tandem t:slim X2™ + G6® CGM

November 2012

Omnipod Tubeless Insulin Pump

September 2016

MiniMed® 670G Pump

# Pump Basics

- Size of a pager

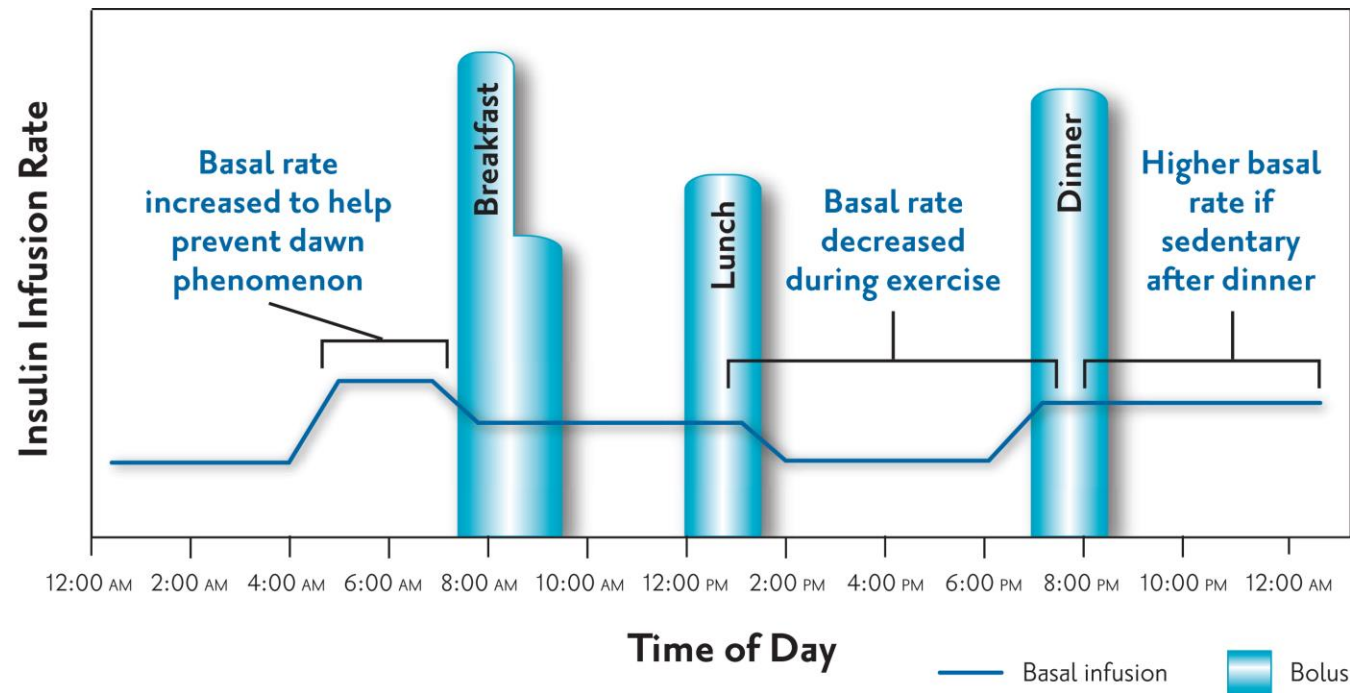

- Insulin is stored in a disposable cartridge (reservoir) and delivered by a small catheter inserted into the SQ fat layer

- The **catheter** (part of an infusion set) and **insulin reservoir** are removed and **changed every 2-3 days**
- Only **ONE** type of Insulin is used (**Humalog**, **Novolog**, **Apidra** ..... **Fiasp**??)
- Infusion-set attachment sites (SQ fatty skin layer) are the same used for MDI therapy:
  - **abdomen, back of the arms, upper buttocks, and thighs**

Insulin Pumps Can Deliver **Customized Basal Infusion Rates** at Increments **as low as 0.01 units/hour** over 24-hours to Modulate Hepatic Gluconeogenesis, avoid Nocturnal Hypoglycemia, etc.

Upon entering food **carbohydrate content** and **blood sugar level**, pumps accurately calculate “**pre-meal**” and glycemic target “**correction**” insulin requisites

# CSII Reduces Incidents of Severe Hypoglycemia

Severe hypoglycemic episodes: CSII vs MDI

Rudolph JW, Hirsch IB. *Endocrine Practice*. 2002; 8:401 – 405.

Bode, BW, Steed RD, Davidson PC. *Diabetes Care*. 1996;19:324-7.

Boland EA, Grey M, Oesterle A, et al. *Diabetes Care*. 1999; 22:1779 – 84.

# In the 5-Nations Study CSII Improved HbA1C without Increased Risk of Hypoglycemia

A1C values are mean  $\pm$  SEM

# CSII Helps Reduce Daily Insulin Requirements in Type 2 Patients

	Insulin		A1C	
	Before CSII	Post 1-Yr CSII Use	Before CSII	Post 1-Yr CSII Use
Patient 1	630 u/day	<b>111 u/day</b>	10.3%	5.7%
Patient 2	402 u/day	315 u/day	10.4%	7.6%
Patient 3	218 u/day	<b>81 u/day</b>	7.5%	6.2%
Patient 4	Patient 4 is not included in this analysis because he was not on CSII for 1 year.			

# Pump Pros and Cons

## PROS

- “**Micro-Management**” of Insulin Delivery → Less glucose variability (**standard deviation**)
- Reduction in number and severity of hypoglycemic episodes → **improved quality of life**
- **No injections**; discreetness of insulin administration
- **Reduced hospitalizations due to hypoglycemia/DKA**
- Patient generally becomes **better educated** & **more independent**
- **Bolus calculator**, prevents insulin stacking; provides **precision of dosing** → **up to 25-30% less insulin**

## CONS

- **Mechanical device attached to body**
- **Perception of weight gain** (not necessarily so)
- **Extra cost** of pump and supplies
- Time and **personnel needed** to initiate, supervise, and fine-tune therapy (**patient participation crucial**)
- **More rapid** (not more frequent) **onset of DKA** if insulin delivery interrupted for extended periods.
- **Infusion site infections** (**rare**) or irritation, leading to inadequate insulin absorption (minimized by **maintaining scheduled visits for remedial care and education**).

# Choosing the Right Candidate

- **Patient is motivated** to accelerate their management and invest time to learn.
- **MDI/Basal-Bolus regimen** no longer meets treatment goals.
- **Patient experiencing .....**
  - **Frequent hypoglycemia**; Hypoglycemic unawareness
  - **Unpredictable fluctuations** in blood glucose levels
  - **Gastroparesis**
- Children/young adults who desire more **life-style flexibility**
- Challenging glycemic control with **adolescent “growth spurt”**
- **Preconception planning and pregnancy**

# Pump Technology Options

## V-Go Insulin Delivery System

- **Wearable insulin delivery device** for adults managing **Type 2 diabetes**.
- **Does not require batteries, electronics, or software** to function.
- **Does not have tubes, cannulas, monitors, or alarms.**
- **Insulin advances via spring-activated hydraulic system**

## Insulin Delivery for **Type 2 Diabetes** worn like a patch

- **It's worn like a patch; Discreet**
- Simply place on skin (such as arm or stomach area), click a button, and wear it 24-hours
- **Use ONE type of insulin (Humalog, Novolog, Apidra)**
- Can translate into **30% less insulin** per day
- “Just Stick It and Click It”

V-Go Option	Preset Basal Insulin Rate Over 24 Hours	+	Available Prandial Insulin <sup>1</sup>	=	Total Available Insulin
VGO 20	20 Units	+	36 U <sup>1,2</sup>	=	56 Units
VGO 30	30 Units	+	36 U <sup>1,2</sup>	=	66 Units
VGO 40	40 Units	+	36 U <sup>1,2</sup>	=	76 Units

# Pump Technology Options

## Tandem: t:slim X2™ Pump + Dexcom G6® CGM

- **Touchscreen technology;** smallest pump available
- Capable of **remote software updates**
- **Integrated Dexcom G6® CGM with Basal-IQ™ Technology:**
  - Acquire Glycemic Data without finger sticks.
  - High and Low alert settings indicate when glucose is above or below a preset target range.
  - **NEW Predictive Low Glucose Suspend Algorithm:** Reduces frequency and duration of hypoglycemic events by predicting glucose levels 30 minutes ahead and suspending insulin if expected to drop below 80 mg/dL.
- **Compatible with iPhone, iPad, iPod touch, any Android Device using OS version 6.0 or later, Android wear watches, Apple watch, etc.**

## Omnipod Tubless Insulin Pump

- **Built-in 200-unit insulin reservoir, angled infusion set**
- **Weighs <30 grams**
- **A Tubeless, Waterproof\*, Bluetooth®-Enabled Pod**
- **Bluetooth®-Enabled Blood Contour Next One Glucose Meter**
- Color Touch-Screen Personal Diabetes Manager
- **NEW Omnipod Dash™ System**
  - Mobile applications for quick/easy access to SmartPhone Personal Diabetes Manager
  - Ability to share status information by SmartPhone with up to 12 people.
  - **Today View Widget** allows **single-screen viewing of CGM and insulin delivery** information on iOS mobile device.
  - Available early 2109

# Pump Technology Options

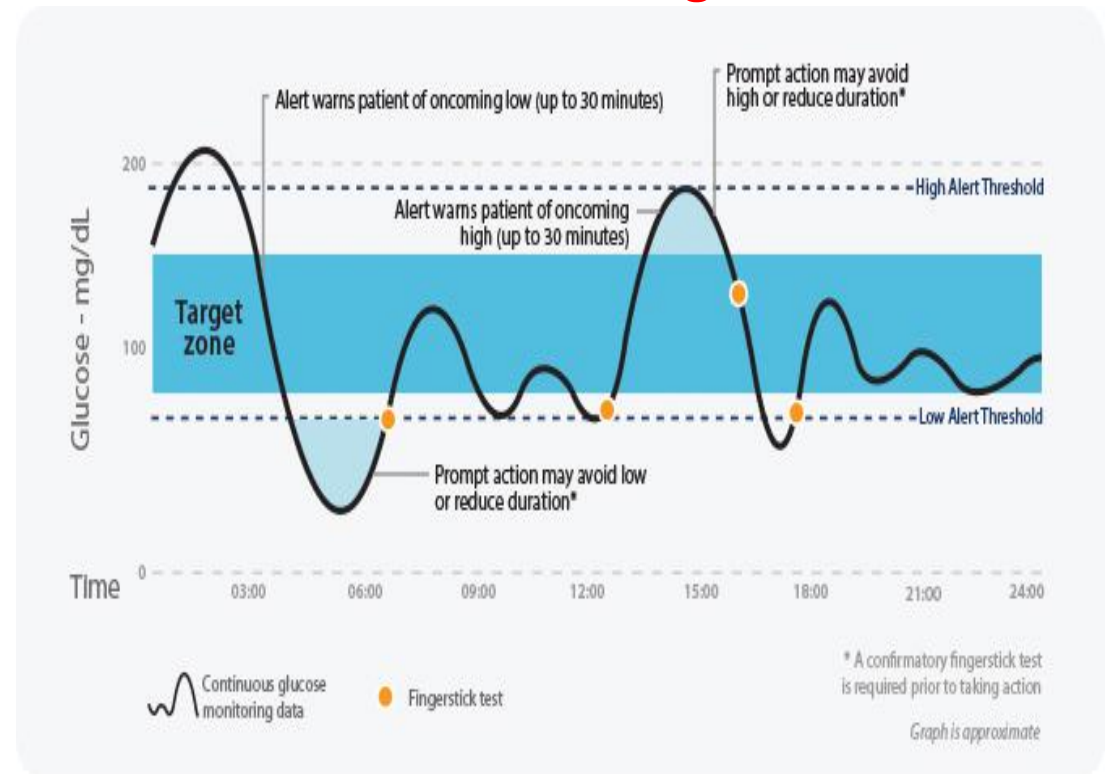

## MiniMed 630G + Guardian™ Sensor 3

### SmartGuard® Technology

- **High Limit**
  - The high limit can be set from 100 to 400 mg/dL.
- **Low Limit**
  - This can be set from 60 to 90 mg/dL.
- **Alert before High**
  - Receive an alert any time the sensor glucose is predicted to reach preset high limit.
- **Time before High**
  - Determines number of minutes (5-30) before reaching high limit that patient receives an Alert.
- **Alert on high**
  - Receive an alert any time sensor glucose reaches or exceeds high limit.
- **Alert before Low**
  - Receive an alert when sensor glucose is predicted to reach low limit in 30 minutes.
- **Alert on Low**
  - Receive an alert when sensor glucose reaches/falls below preset low limit.
- **Suspend on Low**
  - Pump temporarily stops delivering insulin when sensor glucose reaches/falls below pre-set low limit.

## MinMed 630G + Guardian™ Link 3 Transmitter

### Alert Before Low & High Features

# Threshold Suspend/Suspend-On-Low

## Threshold Suspend

### Threshold Suspend

---

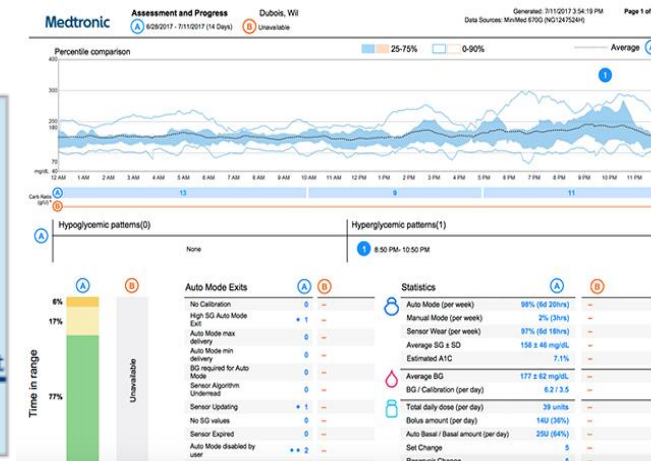

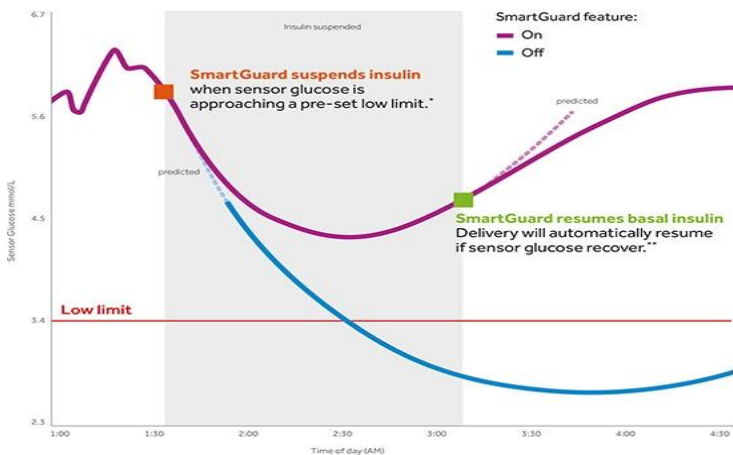

- ▶ Automatically suspends all insulin delivery when sensor values reach or fall below Suspend Threshold
- ▶ Suspend Threshold is set based on your needs

# Pump Technology Options

## MiniMed 670G System: WORLD'S FIRST HYBRID CLOSED LOOP SYSTEM

- SmartGuard® HCL technology (**Guardian® Sensor 3**) offers 3 levels of personalization:
  - **Predictive Alerts** → [Alert Before High](#), [Alert Before Low](#) and [Alert On Low](#) options
  - **Suspend Features** → **BEFORE Low** → **ON Low**:
    - Suspend **BEFORE LOW**: Proactively avoids lows/rebound highs by **stopping insulin 30 minutes before** a pre-selected low limit is reached, then automatically resumes insulin once glucose levels recover ..... all without bothersome alerts.
    - Suspend **ON LOW**: Pump temporarily **stops delivering insulin** when sensor glucose reaches/falls below pre-set low limit.
  - **Auto Mode**: automatically adjusts basal insulin delivery every 5 minutes based upon glucose level to maintain target range of 120 mg/dL, for 24-hours.

# Smart Guard™ Technology: **Suspend-Before-Low**

# Pump or MDI: Which Is Better?

## CSII offers advantages over MDI therapy, but .....

- Properly selecting pump candidates and adequately training them is key to optimal outcomes.
- As technology continues to advance new challenges and opportunities for patients and practitioners will predictably arise.
- **No better time than the present** to become familiar with pump technology and related operational skill set, as the number of patients with **both Type 1 and Type 2 Diabetes** desiring and using pumps will continue to grow.
